## Goal

Provide a ready-to-use fully parametric drawing of the Synchronous Reluctance Rotor with fluid flux-barriers.

The scope of this project is the computation of the flux-barriers points. The drawing scripts are for demonstration purposes only.

## Requirements

Matlab or Octave or Python (NumPy + SciPy) to compute the points. The points calculation is general, so it could be implemented in any language, but I chose Matlab/Octave because it is my standard interface with FEMM software.

If you do not use FEMM, you can still use the calculation part and make a porting for your CAD engine or FEA software. If you do so, consider contributing to the project adding your interface scripting.

## 1 Files needed

For Matlab/Octave, the files needed for the computation are

`calc_fluid_barrier.m`,  
`GetFSolveOptions.m` and  
`isOctave.m`

while for Python it is

`fluid_functions.py`.

## Contacts

You can contact me at [giacomo.bacco@phd.unipd.it](mailto:giacomo.bacco@phd.unipd.it).

If you find a bug, consider opening an issue at <https://github.com/gbacco5/fluid/issues>

## 2 How to use

Open the file `fluid` and run it.

Change the machine data in the data section. All the variables have a comment next to them.

There are some “hidden” options which should be explained.

1. you can provide personal flux-barrier angles, or let the program compute them. This means that you have to always provide the flux-barrier thicknesses and flux-carrier widths. Optionally, you could also provide the electrical flux-barrier angles.

```
1 rotor.barrier_angles_el = [14,26,38]*2;
```

2. if you let the program compute them, they will result the average of the final points  $C'$  and  $D'$  at the rotor periphery. Alternatively, you can define some weights which determine how close  $E$  should be to  $C'$  or  $D'$ .

```
1 rotor.barrier_end_wf = [20,50,80]/100;
```

3. by default, the flux-barrier-end is round, so the code solves an additional system to determine the correct locations of the fillet points. You can skip such system declaring

```
1 rotor.barrier_end = 'rect';
```

and so selecting “rectangular” flux-barrier-end.

4. the inner radial iron ribs are optional, but you are free to provide different widths for every flux-barrier.

```
1 rotor.wrib = [1,2,4]*mm;
```

5. if you also input magnet widths, the rib is automatically enlarged to accommodate the magnet, similarly to an IPM (Interior Permanent Magnet) machine.

```
1 rotor.wm = [10,20,40]*mm;
```

In this case, the output structure `barrier` also contains the location of the magnet base center point.

### 3 Examples

Here are some finished examples based on the output. The drawings are for demonstration purposes only.

## 4 Theory

### 4.1 Flow past a cylinder

Let  $\rho_0$  be the radius of the cylinder,  $\rho, \xi$  the polar coordinate system in use. One possible solution of this problem have these potential and streamline functions:

$$\phi(\rho, \xi) = \left( \rho + \frac{\rho_0^2}{\rho} \right) \cos \xi \quad (1)$$

$$\psi(\rho, \xi) = \left( \rho - \frac{\rho_0^2}{\rho} \right) \sin \xi \quad (2)$$

Although these equations are deeply coupled, the radius  $\rho$  and the phase  $\xi$  can be obtained as a function of the other quantities. For our purposes, we use  $\psi$ .

$$\rho(\psi, \xi) = \frac{\psi + \sqrt{\psi^2 + 4\rho_0^2 \sin^2 \xi}}{2 \sin \xi} \quad (3)$$

$$\xi(\psi, \rho) = \arcsin \left( \frac{\rho \psi}{\rho^2 - \rho_0^2} \right) \quad (4)$$

The velocity field can also be derived through

$$v_\rho(\rho, \xi) = \frac{\partial \phi}{\partial \rho} = \left( 1 - \frac{\rho_0^2}{\rho^2} \right) \cos \xi \quad (5)$$

$$v_\xi(\rho, \xi) = \frac{1}{\rho} \frac{\partial \phi}{\partial \xi} = - \left( 1 + \frac{\rho_0^2}{\rho^2} \right) \sin \xi$$

## 4.2 Conformal mapping

From the reference plane, which is equivalent to a two-pole machine, we use a complex map to obtain the quantities in the actual plane. Let  $p$  be the number of pole pairs. Then:

$$\begin{aligned}\zeta &\xrightarrow{\mathcal{M}} z = \sqrt[p]{\zeta} \\ \rho e^{j\xi} &\xrightarrow{\mathcal{M}} r e^{j\vartheta} = \sqrt[p]{\rho} e^{j\xi/p} \\ \chi + j\eta &\xrightarrow{\mathcal{M}} x + jy\end{aligned}\tag{6}$$

It is easy to find the inverse map:

$$\mathcal{M}: \sqrt[p]{\cdot} \quad \mathcal{M}^{-1}: (\cdot)^p\tag{7}$$

In the transformed plane, the velocities have a different expression:

$$\begin{aligned}v_r(r, \vartheta) &= p \left( r^{p-1} - \frac{R_0^{2p}}{r^{p+1}} \right) \cos p\vartheta \\ v_\vartheta(r, \vartheta) &= -p \left( r^{p-1} + \frac{R_0^{2p}}{r^{p+1}} \right) \sin p\vartheta\end{aligned}\tag{8}$$

This vector field is tangent to the streamlines in every point in the transformed plane. In order to work with this field in  $x, y$  coordinates, we need a rotational map:

$$\begin{aligned}v_x(r, \vartheta) &= v_r \cos \vartheta - v_\vartheta \sin \vartheta \\ v_y(r, \vartheta) &= v_r \sin \vartheta + v_\vartheta \cos \vartheta\end{aligned}\tag{9}$$

## 4.3 Computation of flux-barrier base points

Refer to Figure 1 for the points naming scheme. Keep in mind that  $A'$  is not simply the projection of  $A$  onto the  $q$ -axis, but it represents the original starting point for the barrier sideline, so it lies on the flux-barrier streamline. The same is true for points  $B', B, C', C$ , and  $D', D$ .

Let the flux-barrier and flux-carrier thicknesses and widths be given. Then the base points for the flux-barriers can be computed easily. Let  $D_r$

Figure 1: Flux-barrier base points description.

be the rotor outer diameter,  $w_{\text{rib},t}$  the tangential iron rib width,  $w_{c,k}$  the  $k$ -th flux-carrier width, and  $t_{b,k}$  the  $k$ -th flux-barrier thickness.<sup>1</sup> Then

$$\begin{aligned}
 R_{\text{rib}} &= \frac{D_r}{2} - w_{\text{rib},t} \\
 R_{A'_1} &= R_{\text{rib}} - w_{c,1} \\
 R_{B'_1} &= R_{A'_1} - t_{b,1} \\
 &\vdots
 \end{aligned} \tag{10}$$

where  $R$  represents the radius from the origin. So, in general:

$$\begin{aligned}
 R_{A'_k} &= R_{B'_{k-1}} - w_{c,k} \\
 R_{B'_k} &= R_{A'_{k-1}} - t_{b,k}
 \end{aligned} \tag{11}$$

with the exception  $R_{B'_0} = R_{\text{rib}}$ .

---

<sup>1</sup>You may wonder why the main dimensions of the flux-carrier and flux-barrier differ in the name (width versus thickness). This is due to a choice of mine, because I prefer to refer to width when the flux flows perpendicularly to the dimension, and to thickness when it flows in parallel.

Now we know both the radii and the angle – always  $\pi/(2p)$  – of the flux-barrier internal points. So we can compute their respective streamline value.

#### 4.3.1 Magnet insertion

$$w_{\text{rib},k} \leftarrow w_{\text{rib},k} + w_{\text{m},k}$$

where  $w_{\text{m},k}$  is the  $k$ -th magnet width.

#### 4.3.2 Central base points

We refer to points A and B. If the rib width is zero  $A \equiv A'$  and  $B \equiv B'$ .

The line describing the  $q$ -axis is

$$\begin{aligned} y &= mx + q \\ m &= \tan \frac{\pi}{2p} \\ q &= \frac{w_{\text{rib}}}{2 \cos \frac{\pi}{2p}} \end{aligned} \tag{12}$$

$$\begin{cases} y_A - mx_A - q = 0 \\ x_A - r_A(\psi_{A'}, \vartheta_A) \cos \vartheta_A = 0 \\ y_A - r_A(\psi_{A'}, \vartheta_A) \sin \vartheta_A = 0 \end{cases} \tag{13}$$

where  $\vartheta_A$  is used as the third degree of freedom and  $r_A$  is then a function of it. The solution of such system can be determined solving the single equation

$$r_A(\psi_{A'}, \vartheta_A) (\sin \vartheta_A - m \cos \vartheta_A) - q = 0 \tag{14}$$

in the unknown  $\vartheta_A$ . The function  $r(\psi, \vartheta)$  is simply

$$r(\psi, \vartheta) = \sqrt[p]{\rho(\psi, \vartheta/p)}$$

The same equation can be written for point B with the proper substitution and repeated for all the flux-barriers.

#### 4.4 Outer base points

We refer to points C, D, and E. If the flux-barrier angle,  $\alpha_b$ , is given, then

$$\begin{aligned} x_E &= R_{\text{rib}} \cos\left(\frac{\pi}{2p} - \alpha_b\right) \\ y_E &= R_{\text{rib}} \sin\left(\frac{\pi}{2p} - \alpha_b\right) \end{aligned} \quad (15)$$

Points C and D results from the connection of the flux-barrier sidelines and point E. This connection should be as smooth as possible in order to avoid dangerous mechanical stress concentrations. We are going to use circular arcs to make this connection. So we impose the tangency between the flux-barrier sideline and the arc, between the arc and the radius through point E. The tangent to the sideline can be obtained through the velocity field described above.

Then we want point C to lay on the flux-barrier sideline. These conditions represent a nonlinear system of 4 equations, in 6 unknowns. So we need two more equations, which are that points C and E belong to the fillet circle with radius  $R$ .

$$\begin{cases} x_C - r_C(\psi_C, \vartheta_C) \cos \vartheta_C = 0 \\ y_C - r_C(\psi_C, \vartheta_C) \sin \vartheta_C = 0 \\ (x_C - x_{O_C})^2 + (y_C - y_{O_C})^2 - R_{EC}^2 = 0 \\ (x_E - x_{O_C})^2 + (y_E - y_{O_C})^2 - R_{EC}^2 = 0 \\ (x_{O_C} - x_E)y_E - (y_{O_C} - y_E)x_E = 0 \\ (x_{O_C} - x_C)v_x(r_C, \vartheta_C) + (y_{O_C} - y_C)v_y(r_C, \vartheta_C) = 0 \end{cases} \quad (16)$$

The very same system can be written and solved for point D.

##### 4.4.1 Choice of initial position

For the good convergence of the nonlinear system, we have to choose a proper initial position for the points of interest, namely C and  $O_C$  for the top part of the flux-barrier.

Since point C should be close to E and  $C'$ , a good initial guess could be

$$x_{C(0)} = \frac{x_E + x_{C'}}{2}, \quad y_{C(0)} = \frac{y_E + y_{C'}}{2} \quad (17)$$

A slightly better guess shifts the points a bit to the left, in this way:

$$x_{C^{(0)}} = \frac{x_E + x_{C'} + 0.1x_A}{2.1}, \quad y_{C^{(0)}} = \frac{y_E + y_{C'}}{2} \quad (18)$$

On the other hand, point  $O_C$  lies on one edge of the triangle of vertices  $E, C, O$ , where  $O$  represents the origin and where we are going to use  $C^{(0)}$  instead of  $C$  because it is still unknown. Then:

$$x_{O_C}^{(0)} = \frac{x_E + x_{C^{(0)}} + 0}{3}, \quad y_{O_C}^{(0)} = \frac{y_E + y_{C^{(0)}} + 0}{3} \quad (19)$$

Similar considerations can be made for point  $D$ , with slight changes:

$$x_{D^{(0)}} = \frac{x_E + x_{D'}}{2}, \quad y_{D^{(0)}} = \frac{y_E + y_{D'}}{2} \quad (20)$$

$$x_{O_D}^{(0)} = \frac{x_E + x_{D^{(0)}} + x_C}{3}, \quad y_{O_D}^{(0)} = \frac{y_E + y_{D^{(0)}} + y_C}{3} \quad (21)$$

Notice that here we use point  $C$  which has already been found.

#### 4.5 Flux-barrier sideline points

Consider the top flux-barrier sideline, so the one going from point  $A$  to point  $C$ . We want to create such sideline using a predetermined number of steps,  $N_{\text{step}}$ . From now on, let us call this number  $N$ , and  $N_k$  for the  $k$ -th flux-barrier.

One of the best way to distribute the points along the streamline is to use the potential function,  $\phi$ , defined in Equation 1. We start computing the potential for points  $A$  and  $C$ :

$$\begin{aligned} \phi_A &= \phi(\rho_A, \xi_A) \\ \phi_C &= \phi(\rho_C, \xi_C) \end{aligned}$$

Then, we want to find  $N - 1$  points along the streamline between points  $A$  and  $C$  with a uniform distribution of the potential function. We define

$$\Delta\phi_{AC} = \frac{\phi_C - \phi_A}{N}$$

So we can compute the potentials we are looking for

$$\phi_i = \phi_A + i\Delta\phi_{AC}, \quad i = 1, \dots, N - 1$$

and finally the location of the point with this potential value and the streamline function value required to lie on the flux-barrier sideline. This translates to the following system of equations:

$$\begin{cases} \psi_{AC} - \psi(\rho, \xi) = 0 \\ \phi_i - \phi(\rho, \xi) = 0 \end{cases} \quad (22)$$

The system is well-defined because there are two unknowns and two independent equations. This system must be solved for every flux-barrier sideline point, for the two sides, and for every flux-barrier.<sup>2</sup>

## 4.6 Output

The output of the computation function in Matlab/Octave is one vector of structures (`barrier(:)`) which contains at least two fields (`X` and `Y`). The `X` vector is made in this way:

$$X = \begin{bmatrix} x_E & x_{O_C} & x_C & x_{AC_{N_{\text{step}}-1}} & \cdots & x_{AC_1} & x_A & \searrow \\ x_B & x_{BD_1} & \cdots & x_{BD_{N_{\text{step}}-1}} & x_D & x_{O_D} & x_E & \end{bmatrix}^T$$

and similarly the `Y` vector. So the points are ordered starting from the point `E` and then moving counter-clockwise until `E` is reached again.

---

<sup>2</sup>In Matlab/Octave, the “for every flux-barrier sideline point” loop has been vectorized, while the two sides has been manually split.

## 4.7 Example of Matlab/Octave plot

Here is an example of a Matlab/Octave output plot. The V-shaped lines represent the radii of the fillet arcs, which were not worth to be shown in Matlab/Octave.
